11.3 Design Choices

Component	Design Choice	Description
Time embedding	Time2Vec	Encodes days since first measurement using learned linear and sinusoidal functions. Captures long-term temporal trends and periodic patterns.
	Delta-t	Encodes log-compressed time difference between consecutive measurements. Represents irregular sampling.
Health state encoding	Binary	Encodes each value as within or outside the population reference range. Does not distinguish high vs. low.
	Ternary	Encodes whether the value is low, normal, or high relative to the reference range. Handles asymmetric risk patterns.
Age encoding	Raw values	Uses age directly as numeric input. Assumes linear effects.
	Binned	Discretizes age into groups (e.g., decades) and maps each bin to a learned embedding. Captures nonlinear and threshold effects.
Lab sequence encoding	Raw values	Uses observed biomarker values directly. Preserves absolute clinical scale and keeps preprocessing minimal.
	Within-sequence normalization	Per-sequence z-scoring with learnable scale and shift, then denormalized at output. Stabilizes optimization and improves cross-analyte sharing.
Training objective	Gaussian NLL	Predicts mean and log-variance under a normal distribution. Aligns with conventional RI assumptions. May underperform for skewed or heavy-tailed labs.
	Quantile (pinball) loss	Predicts fixed quantiles (2.5, 25, 50, 75, 97.5%). Distribution-free, robust to skewness and heteroscedasticity.
